PSEUDOMONAS SYRINGAE pv. SYRINGAE hrpZ GENE

The hypersensitive response (HR) of higher plants is characterized by the rapid, localized death of plant cells at the site of pathogen invasion. It occurs during incompatible interactions, which typically involve a microorganism that causes disease only in another plant, and it is associated with resistance against many nematodes, fungi, viruses, and bacteria. The ability of bacteria to elicit HR was first reported in 1963 when Klement and coworkers injected the intercellular spaces of tobacco leaves with high levels of the fluorescent pseudomonads, *Pseudomonas syringae* pv. *syringae* (a pathogen of bean), *Pseudomonas syringae* pv. *tabaci* (a pathogen of tobacco), and *Pseudomonas fluorescens* (a nonpathogen) [see Nature 199:299 (1963); and Phytopathology 54:474 (1964)]. They observed that areas infiltrated with *Pseudomonas syringae* pv. *syringae* collapsed and desiccated within 24 hr, those infiltrated with *Pseudomonas syringae* pv. *tabaci* produced slowly developing and progressively spreading watersoaked lesions, and those infiltrated with *Pseudomonas fluorescens* showed no response. At lower levels of inoculum, *Pseudomonas syringae* pv. *syringae* caused no visible reaction, whereas *Pseudomonas syringae* pv. *tabaci* again caused disease.

The species *Pseudomonas syringae* is remarkable for its pathogenic diversity (Hirano and Upper, 1990). Different strains cause symptoms ranging from galls to "wildfire" blights, well-characterized virulence (symptom enhancing) factors are as diverse as phytohormones and peptide toxins, multiple patterns of host specificity (including in some cases, avr-mediated gene-for-gene interactions) involve virtually all crop plants, and plant associations vary from epiphytism to devastating pathogenesis. There is a *Pseudomonas syringae* version for many important phenomena in the interactions of plants and pathogenic microbes, and this species has accordingly attracted much investigation. These early observations led many investigations into the study of the underlying mechanisms of HR. It is now known, for example, that a pathogen at lower concentrations in an incompatible host causes the HR in scattered, individual plant cells (with one

bacterium in the leaf intercellular space triggering the death of one plant cell), and that the macroscopic HR is a manifestation of a cellular hypersensitivity that can operate under natural conditions [see Phytopathology 64:885 (1974)]. It is also known that elicitation of the
5 HR requires a bacterium that is able to synthesize proteins and is probably in contact with the surface of the doomed plant cell [see Phytopathogenic Prokaryotes, vol. 2, Mount and Lacy, eds., Academic Press, pp 149-177 (1982)]. However, the *Pseudomonas syringae* molecule that actually elicits the HR (and paradoxically, also appears
10 essential for pathogenesis) has remained elusive.

The ability of *Pseudomonas syringae* strains to elicit the HR or pathogenesis in nonhost or host plants, respectively, is controlled by *hrp* genes, and typical Hrp mutants have the null phenotype of a nonpathogen in all plants [see Proc. Natl. Acad. Sci. USA 82:406 (1985);
15 J. Bacteriol. 168:512 (1986); and Mol. Plant-Microbe Interact. 4:132 (1991)]. *hrp* genes are clustered, and some appear to be widely conserved in Gram-negative bacterial pathogens that cause eventual necrosis in their hosts. These pathogens include *Pseudomonas syringae*,
20 *Pseudomonas solanacearum*, *Xanthomonas campestris*, *Erwinia amylovora*, *Erwinia stewartii*, and *Erwinia chrysanthemi* [see Mol. Plant-Microbe Interact. 5:390 (1992)]. The *hrp* clusters from *Pseudomonas syringae* pv *syringae* 61 (which has been deposited with the American Type Culture Collection under the provisions of the Budapest Treaty and which is designated as ATCC 55427) and *Erwinia*
25 *amylovora* Ra321 are unique in that they enable nonpathogenic bacteria to elicit the HR in tobacco and other plants [see J. Bacteriol. 170:4748 ((1988); and Advances in Molecular Genetics of Plant-Microbe Interactions, vol. 2, Nester and Verma, eds., Kluwer Academic Publishers, pp 53-60 (1991)]. Thus, a 25-kb cluster of *Pseudomonas*
30 *syringae* pv *syringae* 61 *hrp* genes is sufficient for the HR phenotype (but not the pathogenic phenotype) of the bacterium [see J. Bacteriol. 170:4748 (1988)].

Early research leading to the present invention involving *TnphoA* mutagenesis and complementation analysis of the HR-active cluster of

Pseudomonas syringae pv *syringae* 61 *hrp* genes carried on cosmid pHIRII enabled us to initially identify 13 complementation groups at the cistron level, including two that encode envelope proteins [see Mol. Plant-Microbe Interact. 4:469 (1991), the disclosure of which is incorporated *in toto* herein]. All of the *TnphoA* mutations in complementation groups II through XIII have strong *Hrp* phenotypes, including loss of the ability to multiply or cause disease in bean plants and to elicit the HR in tobacco cells. DNA sequence analysis of the two genes encoding envelope proteins revealed that the *hepH* (group X) product is similar to outer membrane proteins involved in protein or phage secretion in many Gram-negative bacteria, and *HrpI* (group IV) is a member of a superfamily of inner membrane proteins with an apparent function in protein secretion regulation [see J. Bacteriol. 174:4338 (1992); and J. Bacteriol. 174:6878 (1992)]. Putative open reading frames for these proteins have also been reported in *Pseudomonas solanacearum* and *X. campestris* pv *vesicatoria*, and *Erwinia amylovora* has been shown also to produce a *HrpI* protein [see Mol. Plant-Microbe Interact. 5:390 (1992); and Mol. Plant-Microbe Interact. 5:384 (1992)]. These observations support the hypothesis that some of the conserved *hrp* genes are involved in the secretion of one or more proteins that elicit the HR in nonhosts and are required for pathogenesis in hosts. A protein elicitor of the HR, named harpin, has been isolated from *Erwinia amylovora* Ea321, the fire blight pathogen of rosaceous plants [see Science 257:85 (1992), the disclosure of which is incorporated *in toto* herein]. Harpin is a heat-stable, cell envelope-associated protein with an apparent molecular mass of 44 kDa. Mutants deficient in the cognate *hrpN* gene are unable to elicit the HR in tobacco leaves or to produce symptoms in highly susceptible, mature pear fruit.

Identification of the *Pseudomonas syringae* HR elicitor would be particularly useful, because this species and its many pathovars have become a model for investigating several key phenomena in plant-pathogen interactions. Unfortunately, attempts to use the *Erwinia amylovora* *hrpN* gene and antibodies to its product failed to reveal a corresponding *Pseudomonas syringae* pv *syringae* elicitor; no *hrpN*

homolog by low stringency probing of Southern blotted *Pseudomonas syringae* pv *syringae* 61 hrp DNA and no cross-reactive proteins in immunoblots of proteins from bacteria actively expressing the *Pseudomonas syringae* pv *syringae* 61 hrp genes we able to be located
5 by these methods, and it was also not possible to detect elicitor activity in cell-free extracts or culture fluids of bacteria expressing these hrp genes. Nevertheless, the observation that HrpH is required for the HR suggested that the *Pseudomonas syringae* pv *syringae* 61 HR
10 elicitor is also a secreted protein, albeit a protein that is dissimilar in primary structure and more elusive than the *Erwinia amylovora* harpin. To find such a protein we developed an *in situ* lysis procedure, one aspect of the present invention, that enabled us to directly screen an expression library of *Pseudomonas syringae* pv *syringae* 61 harpin genes for HR eliciting activity.

15 Thus, the hrp genes are the common denominator underlying the pathogenic diversity of *Pseudomonas syringae*, and the elucidation of hrp gene functions in this species could have broad explanatory power. We have discovered and describe herein that the biologically active product of the *Pseudomonas syringae* pv *syringae* 61 hrp cluster is an
20 extracellular 34.7 kDa protein, harpin_{PSS}. Harpin_{PSS} is secreted to the extracellular milieu in a hrp-dependent manner and is the first protein clearly demonstrated to reach the extracellular milieu via the recently discovered Hrp secretion pathway.

Utilizing the *in situ* lysing technique, we are now able to
25 describe another aspect of the present invention, specifically that complementation group XII in the *Pseudomonas syringae* pv *syringae* 61 hrp cluster encodes a 34.7 kDa protein that is secreted in a hrpH-dependent, elicits the HR in tobacco leaves, and possesses elicitor information in a carboxyl-terminal region with repeated amino acid
30 sequences. The protein designated harpin_{PSS}, is dissimilar in its amino-acid sequence to the *Erwinia amylovora* harpin_{Ea}, but the two harpins are similar in several other properties that predict common structural features of a class of proteins with HR-eliciting activity. We used Southern blot analysis to determine that a homolog of the

harpin_{PSS}-encoding hrpZ gene is present in several important strains in different pathovars of *Pseudomonas syringae*. Finally, metabolic inhibitors (α -amanitin, cycloheximide, sodium vanadate and lithium chloride (Sigma Chemical Co.)) were used to

- 5 demonstrate that the HR elicited by harpin_{PSS} in tobacco results from an active response of the plant. Pathogenicity, parasitic compatibility, hypersensitivity, and host range determination are central phenomena in plant-microbe interactions that are particularly approachable with the *Pseudomonas syringae* pathogens. The discovery of a molecule that
10 mediates essential interactions of *Pseudomonas syringae* with plants should accelerate molecular explanation of these phenomena.

These and other aspects of the present invention will become more apparent with regard to the following figures, examples and detailed description of the present invention.

- 15 In the figures,

Figure 1 depicts a restriction map of pHIR11 subclones producing an HR elicitor according to the present invention;

- Figure 2 depicts a diagram of the hrpZ fragments used to test the role of conserved or repeated amino acid sequences in the elicitor
20 activity of Harpin_{PSS} according to the present invention;

Figure 3 depicts the SDS-PAGE analysis of Harpin_{PSS} and Harpin_{PSS} Δ 125 proteins produced by *E. coli* transformants before and after purification according to the present invention;

- Figures 4A, 4B and 4C depict immunoblots showing the
25 equivalence of the Harpin_{PSS} proteins produced by *E. coli*(pSYH4) and *Pseudomonas syringae* pv *syringae* 61 and the hrpH-dependent secretion of harpin_{PSS} in 61 cultures grown in minimal media according to the present invention;

- Figure 5 provides Southern blot evidence that three strains of
30 *Pseudomonas syringae* according to the present invention carry a hrpZ homolog; and

Figure 6 depicts immunoblot showings for harpin_{PSS} homologs in three additional strains of *Pseudomonas syringae*.

More specifically, Figure 1 contains a top line indicating pHIR11 and complementation groups (determined by *TnphoA* mutagenesis) and putative transcription units (determined by *Tn-gusA1* mutagenesis and DNA sequence analysis) that comprise the *hrp* cluster [see Mol. Plant-Microbe Interact. 4:469 (1991); Huang et al., Characterization of the *Pseudomonas syringae* pv. *syringae* *hrpJ* and *hrpI* genes: homology of HrpI to a superfamily of proteins associated with protein translocation, Mol. Plant-Microbe Interact. in press (1993); and J. Bacteriol. 174:1734 (1992)]. The two genes encoding secretion-related envelope proteins (*hrpI* and *hrpH*) and the elicitor gene (designated *hrpZ*) are identified. The complementation group A (*hrmA*) is not required for pathogenesis, and the complementation groups A, I, and II have been defined by both *TnphoA* and *Tn-gusA1* insertions [see Mol. Plant-Microbe Interact. 4:469 (1991); Huang et al., Characterization of the *Pseudomonas syringae* pv. *syringae* *hrpJ* and *hrpI* genes: homology of HrpI to a superfamily of proteins associated with protein translocation, Mol. Plant-Microbe Interact. in press. (1993); and J. Bacteriol. 174:1734 (1992)]. pSYH1 and pSYH4 were identified in a random library of pHIR11 subclones by their HR-eliciting activity in tobacco leaves. Subclones pSYH5 and pSYH8 are derivatives of pSYH1; all others are from pSYH4. The products of these subclones were analyzed on SDS-PAGE gels and indicate that the 32-kDa protein is a derivative of the 42-kDa protein with a truncated amino terminus. The hatched boxes denote the extent of the *hrpZ* open reading frame present in each subclone; B refers to BamHI; Bg refers to BfIII; E refers to EcoRI; H refers to HindIII; and V refers to EcoRV.

With regard to Figure 2, the subclones and deletion derivatives of *hrpZ* were constructed in pBluescript by exploiting the restriction sites (shown in the top line in the figure and in the DNA sequence depicted below) as described in the following examples. Open bars depict the HrpZ product of each plasmid, with the amino terminus at the left. pSYH10 carries the complete *hrpZ* open reading frame, and has been deposited as *E. coli* DH5 α (pSYH10) with the American Type Culture Collection in accordance with Budapest Treaty provisions. The deposit

number is ATCC 69317. The solid bar denotes the 22 amino acid region showing similarity with harpin_{Ea} (see the DNA sequence depicted below). The hatched bars denote the GGGLGTP direct repeats; the stippled bars denote the QTGT direct repeats. PMSF-treated soluble
5 extracts of sonicated *E. coli* DH5 α transformants were assayed for their ability to elicit a typical HR in tobacco leaves following the procedure outlined in Beer [see Science 257:85 (1992)] wherein "+" depicts the HR, and "-" depicts no response observed.

With regard to Figure 3, an SDS-12% PAGE gel prepared using
10 conventional techniques and stained with coomassie blue, shows the partial purification resulting from heat treatment of crude elicitor preparations according to the present invention and the further purification resulting from electrophoresis through 4% NuSeive agarose (FMC) and subsequent electroelution. Lanes 1, 2 and 5 shows total
15 protein extracts from *E. coli* DH5 α (pBluescript), DH5 α (pSYH1) and DH5 α (pSYH4), respectively; 3 and 6 shows soluble proteins in heat-treated sonicates from DH5 α (pSYH1) and DH5 α (pSYH4); 4 shows gel-purified harpin_{PSS} Δ 125 from DH5 α (pSYH1); and 7 indicates gel-purified harpin_{PSS} from DH5 α (pSYH4). The molecular masses (kDa) of
20 commercial standard marker proteins are shown at the left.

With regard to Figures 4A, 4B and 4C, bacteria were grown in King's B medium to an OD₆₀₀ of 0.5 to 0.8, and then incubated for 24 hours in either minimal medium or in King's B as described in more detail in Example III. The cell and extracellular fractions were then
25 separated by centrifugation and boiled in SDS loading buffer before proteins were resolved by electrophoresis through a 10% polyacrylamide gel and either immunoblotted and probed with anti-harpin_{PSS} antibodies (A and B) or stained with coomassie blue (C). The molecular masses (kDa) of marker proteins are shown at the left of
30 each figure.

More specifically, Figure 4A depicts an immunoblot probed with anti-harpin_{PSS} antibodies and visualized with goat anti-rabbit antibody conjugated with alkaline phosphatase, showing identical mobilities of the harpin_{PSS} proteins produced by *E. coli* DH5 α (pSYH4) and

Pseudomonas syringae pv *syringae* 61. Lane 1 shows purified harpin_{PSS} from *E. coli* DH5 α (pSYH4); 2 shows lysates of *Pseudomonas syringae* pv *syringae* 61 cells grown in minimal media. More specifically, Figure 4B depicts an immunoblot showing that the production of extracellular harpin_{PSS} in *Pseudomonas syringae* pv *syringae* is dependent upon *hrpH*, *hrpZ*, and *hrp*-derepressing minimal medium. Lane 1 shows the cell fraction from strain 61 in King's B medium; 2 shows the extracellular fraction from strain 61 in King's B medium; 3 shows the cell fraction from strain 61 in minimal media; 4 shows the extracellular fraction from strain 61 in minimal medium; 6 shows the extracellular fraction from 61-2089 in minimal medium; 7 shows the cell fraction from *hrpZ* mutant 61-2092 in minimal medium; and 8 shows the extracellular fraction from 61-2092 in minimal medium. More specifically, Figure 4C depicts the coomassie-stained SDS-PAGE gel of the same samples that were analyzed in lanes 3 - 8 shown in Figure 4B. Lanes 1 through 6 are in register with lanes 3 through 8 above, and show that the secretion of harpin_{PSS} to the extracellular fraction is not a result of cell lysis.

More specifically, the Southern blot depicted in Figure 5 shows the hybridization of a *hrpZ* probe with EcoR1 fragments in pHIR11 (lane 1), and in the genomic DNA of *Pseudomonas syringae* pv *syringae* B728a (lane 2). *Pseudomonas syringae* pv *glycinea* race 4 (lane 3), and *Pseudomonas syringae* pv *tomato* DC3000 (lane 4). Similarly digested DNA of *X. campestris glycines* (lane 5) failed to hybridize. The probe used in collecting this data was the 0.75 kb BstX1 internal fragment of the *hrpZ* gene shown in the sequence below, labelled with ³²P-dCTP using Prime-it II (Statagene) following the manufacturer's instructions. Hybridization was performed with the Immobilon-N membrane (Millipore) at moderate temperatures of 58 - 60° C for 14 hours. The membrane was then washed in 2 X SSC containing 0.1% SDS for 15 minutes at room temperature, followed by an additional wash in 0.1 X SSC containing 0.5% SDS for 1 hour at 58 - 60° C. Autoradiography was done at -80° C for 3 hr (lanes 1, 2, 3, 5) and 7 hr (lane 4) using Kodak X-

Omat AR films. The size of standard marker fragments are shown at the left.

With specific regard to Figure 6, there is seen immunoblots prepared from other *Pseudomonas syringae* strains. To obtain these immunoblots, cultures were grown for 24 hr in minimal medium and sonicated directly in the culture medium. Proteins were resolved by SDS-10% PAGE and immunostained as in Figure 4A. Lane 1 shows *Pseudomonas syringae* pv *syringae* 61; 2 shows *Pseudomonas syringae* pv *syringae* B728a; 3 shows *Pseudomonas syringae* pv *glycinea* race 4; 4 shows *Pseudomonas syringae* pv *tomato* DC3000; 5 shows *Pseudomonas fluorescens* 55. The molecular masses (kDa) of standard marker proteins are shown at the left.

In the following description, plants of commercially available species of tobacco (*Nicotiana tabacum* L. cv. Samsun), tomato (*Lycopersicon esculentum* Mill. cv. Pearson), soybean (*Glycine max* L. cv. Norchief), potato (*Solanum tuberosum* L. cv. Katahdin), and bean (*Phaseolus vulgaris* L. cv. Pinto) were grown in a greenhouse at 23-25° C with a photoperiod of 16 hours. *A. thaliana* (Co-1) plants were grown at 21-23° C with a photoperiod of 16-24 hours.

The laboratory technique used in the following description of the present invention to demonstrate the HR is straight-forward. The intercellular spaces of tobacco leaves are infiltrated by first puncturing a sector on a leaf with a common straight dissecting needle. Then a 1-ml capacity syringe (without a needle), containing 0.1-0.5 ml of a bacterial cell suspension (usually 10^7 - 10^8 viable cells/ml) of bacteria is pressed against one side of the leaf directly over the puncture. While pressing a finger on the opposite side of the leaf to stabilize it and to prevent liquid from leaking out of the punctured area, the syringe plunger is pressed gently to introduce the bacterial suspension into the leaf. Infiltration is considered successful when a water-soaked area approximately 1-4 cm² appears in the leaf. Infiltration of plant leaves with harpin_{pss} preparations (in 5 mM phosphate buffer, pH 6.5) or bacteria (in 10 mM MgCl₂) is described below.

All DNA manipulations described herein, except when specified, followed conventional protocols [see Ausubel, et.al., Current protocols in molecular biology, John Wiley (1987); and Sambrook, *supra*]. DNA sequencing was performed using the Sequenase Version 2.0 kit (U.S. Biochemical). Sequences were analyzed with the Genetics Computer Group Sequence Analysis Software package [see Gene 12:387 (1984)].

The two *Pseudomonas syringae* pv *syringae* TnphoA mutants used, 61-2089 and 61-2092, were constructed previously [see Mol. Plant-Microbe Interact. 4:469 (1991)]; the *Pseudomonas syringae* pv *glycinea* race 4 (a pathogen on some cultivars of soybean), *Pseudomonas syringae* pv *tomato* strain DC3000 (a pathogen on some cultivars of tomato), as well as *A. thaliana* were obtained from various sources; and *Pseudomonas fluorescens* 55 (a nonpathogen) has been previously reported [see J. Bacteriol. 170:4748 (1988)]. The *E. coli* strain used primarily was DH5 α (Bethesda Research Laboratories) [see J. Mol. Biol. 166:557 (1988)]; and MC4100 [see Silhavy et al., Experiments with gene fusions, Cold Spring Harbor (1984)] were used in those experiments where the Hrp⁺ phenotype of pHIR11 needed to be observed. pHIR11 a cosmid clone containing a 25-kb, hrp gene cluster of *Pseudomonas syringae* pv *syringae* 61 and enables nonpathogenic bacteria, such as *Pseudomonas fluorescens* and many RecA⁺ strains of *E. coli*, to elicit the hypersensitive response in plants [see J. Bacteriol. 170:4748 (1988)]. pSYH1 and pSYH4 are subclones of pHIR11 in pBluescript SK (Statagene) containing the hrpZ gene of *Pseudomonas syringae* pv *syringae*. The microorganisms described herein, whether used for making of the present invention or as screens to demonstrate utility, were obtained from commercial sources, from the authors of previous publications cited herein, or have been deposited with the American Type Culture Collection (Bethesda, Maryland). In addition, the microorganisms described herein are maintained in the Department of Plant Pathology at Cornell University (Ithaca, New York) and will be maintained and made available to investigators requesting the same from the Department of Plant Pathology under provisions equivalent to the Budapest Treaty.

Pseudomonads were routinely grown in King's B broth [see J. Lab. Med. 22:301 (1954)] at 30° C unless the cultures specify the hrp-derepressing minimal medium of Huynh [see Science 245:1374 (1989)], adjusted to pH 5.5. *E. coli* was grown in LM or Terrific Broth [see 5 Sambrook et al., Molecular Cloning: A Laboratory Manual, 2nd ed., Cold Spring Harbor Laboratory (1989)] at 37° C for plasmid extraction and at 30° C for protein expression. Plasmids were introduced into bacteria by chemical transformation following recognized techniques reported by Sambrook, *supra*, or electroporation using a Gene Pulsar (Bio-Rad) 10 according to the manufacturer's directions.

A rapid procedure for identifying harpin_{PSS}-producing recombinant *E. coli* based on *in planta* bacterial lysis is described in the following example.

EXAMPLE I

15 Partial *Sau*3A subclones of pHIR11 (inserts of 1.5 - 3.5 kb were established in pBluescript SK(-) and maintained in *E. coli* DH5 α using conventional techniques. 200 randomly chosen transformants were screened for HR-eliciting activity in tobacco leaves. Transformants were grown with constant shaking in Terrific Broth with 1 mM IPTG at 20 room temperature. Bacteria were harvested by centrifugation and incubated for 10 min in a solution consisting of 50 mM glucose, 25 mM Tris-HCl (pH 8.0), and 10 mM EDTA at an OD₆₀₀ of 0.4 to 0.6. This treatment rendered the bacterial outer membrane permeable to . macromolecules such as lysozyme which lyses bacteria. Cells were 25 then collected by centrifugation and resuspended in the same volume of 10 mM Tris-HCl (pH 8.0) containing 2 mg/ml lysozyme. The suspension was immediately infiltrated into tobacco leaves. The HR phenotype was recorded 24 hours later.

30 Harpin_{PSS}, according to the present invention, was purified to homogeneity using the following example.

EXAMPLE II

E. coli DH5 α cells containing appropriate plasmids were grown in Terrific Broth at 30° C overnight in the presence of 1 mM IPTG.

Bacteria were harvested by centrifugation, the pellet washed once in 10 mM phosphate buffer (pH 6.5), and resuspended in one-tenth volume of the same buffer supplemented with 1 mM phenylmethylsulfonyl fluoride (PMSF, a serine protease inhibitor).

5 The cells were then disrupted by sonication using a Sonicator Ultrasonic Cell Disruptor™ (Heat System-Ultrasonics) at a power output of 4, and the pulsar cycle timer set to 40% duty cycle (under these conditions, 10 ml of bacterial suspension were sonicated for 10 min on ice). The sonicate was incubated at 100° C for 10 min, followed
10 by centrifugation at 16,500 x g for 20 min. Proteins in the supernatant were separated by conventional horizontal agarose gel electrophoresis in a buffer consisting of 0.025 M Tris, 0.192 M glycine, pH 8.3. Agarose regions containing individual proteins were excised, and the proteins were eluted from the excised blocks of Agarose using an Elutrap
15 apparatus (Schleicher and Schuell) following the manufacturer's directions. The eluate was desalted by passage through Sephadex G-25 spin columns. Conditions for SDS-polyacrylamide gel electrophoresis and immunoblotting were the same as reported by He [see J. Bacteriol. 173:4310 (1991)].

20

The detection of elicitor activity in the extracellular fluids of cultures *Pseudomonas syringae* pv *syringae* was conducted as described in the following example.

EXAMPLE III

25 *Pseudomonas syringae* pv *syringae* strains 61 and 61-2089 were first grown in 50 ml King's B broth at 30° C to an OD₆₀₀ of 0.5 to 0.8. Cells were collected by centrifugation, washed once in 5 ml of *hrp*-derepressing minimal medium [see Science 245:1374 (1989)], resuspended in 50 ml of the same medium, and incubated, with shaking,
30 overnight. The cultures were centrifuged at 27,000 x g for 30 min and the resulting supernatants were immediately put into a boiling water bath for 10 min, dialyzed against 200 volumes of 10 mM MES (pH 5.5) and 1 mM PMSF overnight, and concentrated 50-fold by ultrafiltration with Centricon 10 tubes (Amicon). The concentrated supernatants were

then diluted to various degrees with the same buffer and infiltrated into tobacco leaves. HR symptoms were recorded 24 hours later.

- 5 The construction and analysis of *hrpZ* derivatives according to the present invention producing truncated harpin_{PSS} polypeptides was conducted according to the following example.

EXAMPLE IV

- pSYH12 [Figure 2] was derived from pSYH5 by digestion with *MscI* and *KpnI*, treatment with T4 DNA polymerase, and religation. pSYH14 carries the 0.73 kb *MscI*-*EcoRV* fragment of pSYH5 in the *EcoRV* site of Bluescript SK(-); pSYH26 carries the T4 DNA polymerase-treated 0.6 kb *Avall*-*EcoRV* fragment from pSYH5 in the *EcoRV* site of pBluescript; and pSYH32 carries the T4 DNA polymerase-treated 0.73 kb *PvuII*-*EcoO1091* fragment of pSYH5 in the *SmaI* site of pBluescript SK(-). All constructs resulted in translational fusions with the amino-terminal 30 to 41 amino acids of β -galactosidase and translational terminations at either the *hrpZ* stop codon (pSYH14 and pSYH26) or the stop codons in the pBluescript SK(-) multiple cloning region (pSYH12, pSYH32, and pSYH33). Elicitor activity assays were initiated by growing *E. coli* DH5 α transformants overnight at 30° C in Terrific Broth and in the presence of 0.5 mM IPTG. Cells were collected by centrifugation, washed twice in 5 mM MES (pH 5.5), resuspended in one-fifth volume of the same buffer containing 1 mM PMSF, and disrupted by sonication. The sonicates were centrifuged at 16,500 x g for 10 min. and the supernatant fraction was infiltrated into tobacco leaves.

- As described, a screening procedure employing *in planta* bacterial lysis facilitated identification of *E. coli* transformants expressing a *P. syringae* HR elicitor according to the present invention. The ability of pHIR11 to confer HR-eliciting activity on nonpathogenic bacteria suggested to us that its *hrp* cluster may be carrying a gene encoding the elicitor, and thus an expression library of partially digested *Sau3A* fragments (1.5-3.5) of pHIR11 in pBluescript SK was prepared and *E. coli* transformants was screened for HR-eliciting activity in tobacco

leaves. Previous observations suggested that the use of an *in situ* lysis technique would facilitate detection of elicitor activity. Earlier reports had noted that the *envA1* mutation that confers outer membrane leakiness in *E. coli* MB5504 could not phenotypically suppress the *hrpH* mutation in pHIR11 [see J. Bacteriol. 174:6878 (1992)], which led us to believe that an elicitor produced by *hrp* subclones in the absence of other *hrp* genes might be cytoplasmic and therefore detectable only after cell lysis. Subsequent to the present invention, it had not been observed that any elicitor activity could be determined in culture fluids or sonicated extracts of *E. coli* MC4100 (ATCC deposit no. 35695)(pHIR11), *Pseudomonas fluorescens* 55(pHIR11), and *Pseudomonas syringae* pv *syringae* 61(pHIR11) treated with 1 mM phenylmethylsulfonyl fluoride (PMSF, a serine protease inhibitor). This suggested to us that the elicitor might be quite labile.

To circumvent the preparation of lysates *ex planta*, we developed (Example I) one aspect of the present invention, a procedure for lysing *E. coli* cells in plants through treatment with EDTA and lysozyme at the time of inoculation. Two out of 200 randomly chosen *E. coli* transformants (1.0%) screened by this technique were found to produce the rapid leaf tissue collapse characteristic of the HR. Collapse did not occur when the lysis step was omitted, or when the lysis was performed on *E. coli* DH5 α cells lacking these two subclones. Plasmids pSYH1 and pSYH4 were isolated from the two positive transformants.

Overlapping subclones produced harpinpss and a truncated derivative, both of which possessed heat-stable, HR-eliciting activity. Restriction maps of pSYH1 and pSYH4 (Figure 1) show that the inserts in the two plasmids overlapped in a 2.0-kb region that corresponded with complementation group XII of pHIR11. Interestingly, the two plasmids expressed proteins of different sizes as shown by SDS PAGE analysis; pSYH1 expressed a 32 kDa protein, and pSYH4 expressed a 42 kDa protein. Both proteins remained soluble and retained >85% of their elicitor activity after incubation at 100° C for 10 min, which facilitated rapid, partial purification. Following purification to homogeneity by electrophoresis through 4.0% agarose, the proteins

elicited the HR in tobacco leaves at 0.6 μ M (32 kDa protein) and 2.4 μ M (42 kDa protein). Further subcloning revealed that the 32 kDa protein was a truncated product of the 42 kDa protein. Thus, the truncated derivative was 4-times more potent than the full-length protein in eliciting the HR. Following convention, the name harpin_{pss} has been used for the 42 kDa protein to distinguish it from the *Erwinia amylovora* harpin reported by Beer [see Science 257:85 (1992)] which we now refer to as harpin_{Ea}. The 32 kDa protein encoded by pSYH4 has an amino-terminal deletion of 125 amino acids and accordingly is referred to as harpin_{pss} Δ 125. Harpin_{pss} appears to be the only HR elicitor encoded by pHIR11; no other clones showed any HR-eliciting activity.

We have also shown herein that harpin_{pss} is produced by *Pseudomonas syringae* pv *syringae* 61 in a minimal medium that derepresses *hrp* gene expression, and that the protein is secreted in a *HrpH*-dependent manner. To show this, antibodies were raised in rabbits against the 42 kDa harpin_{pss} protein purified from *E. coli* DH5 α (pSYH4), using conventional techniques, and used to probe immunoblotted SDS-PAGE gels loaded with the same protein and with proteins from *Pseudomonas syringae* pv *syringae* 61. The *Pseudomonas syringae* pv *syringae* 61 cultures were grown in either King's B medium or in *hrp*-derepressing minimal medium. Both cell lysate and culture fluid fractions were then analyzed. Figure 4A shows that *Pseudomonas syringae* pv *syringae* 61 produced a protein that cross-reacted with the anti-harpin_{pss} antibodies and had the same mobility as the purified harpin_{pss}. Figure 4B shows that this protein was not produced by *Pseudomonas syringae* pv *syringae* 61 in King's medium, which represses *hrp* gene expression [see Science 245:1374 (1989); Appl. Environ. Microbiol. 55:1724 (1989); J. Bacteriol. 174:3499 (1992); and J. Bacteriol. 174:1734 (1992)]; nor was this protein produced by *hrpZ* mutant *Pseudomonas syringae* pv *syringae* 61-2092. The results confirm the production of the 42-kDa harpin_{pss} protein by wild-type *Pseudomonas syringae* pv *syringae* 61 and argue against any apparent *hrp*-dependent posttranslational processing of the protein.

To determine the localization of harpin_{PSS} in *Pseudomonas syringae* pv *syringae* 61, cultures were grown for 24 hr in hrp-derepressing minimal medium, fractionated by centrifugation, and then analyzed for the distribution of harpin_{PSS} by immunoblotting on SDS-PAGE gel and probing with anti-harpin_{PSS} antibodies. As shown in Figure 4B, more than half of the harpin_{PSS} was found in the culture supernatant. Coomassie blue staining of the total protein in the culture supernatant and cell lysate demonstrated that the release of harpin_{PSS} could not be attributed to cell lysis, as shown in Figure 4C. Moreover, Figure 4B shows that harpin_{PSS} was not secreted to the medium of the *hrpH* mutant *Pseudomonas syringae* pv *syringae* 61-2089. *hrpH* encodes an envelope protein with sequence similarity to outer membrane proteins known to be involved in protein or phage secretion in several Gram-negative bacteria, and the protein is required for *Pseudomonas syringae* pv *syringae* 61 to elicit the HR. As predicted, harpin_{PSS} was produced, but retained, in *hrpH* cells. Thus, harpin_{PSS} is an extracellular protein secreted via the *Hrp* secretory pathway, and its transport is essential for elicitation of the HR.

The observation that harpin_{PSS} was secreted suggested that the extracellular fluids of *Pseudomonas syringae* pv *syringae* cultures grown in hrp-derepressing medium should possess elicitor activity, despite our previous failure to detect it. The dialyzed supernatant of a culture of *Pseudomonas syringae* pv *syringae* 61 was, indeed, found to elicit a typical HR in tobacco leaves, but only if heated to 100°C for 10 immediately upon harvest, dialyzed in the presence of PMSF, and then concentrated >30-fold by ultrafiltration. Identically prepared supernatants from a culture of *Pseudomonas syringae* pv *syringae* 61-2089 failed to elicit HR.

The DNA sequence analysis of *hrpZ* according to the present invention revealed its product harpin_{PSS} to be a glycine-rich protein with no extensive similarity to known proteins. The nucleotide sequences of the DNA inserts in pSYH10 and pSYH5 were determined using conventional techniques in the art, and are shown below in the

DNA sequence of the *hrpZ* gene (Seq. No. 3) according to the present invention:

- 15 The DNA sequence of the *Pseudomonas syringae* pv *syringae* 61 DNA fragment that is carried in pSYH10 and contains the complete hrpZ open reading frame is shown above along with relevant restriction sites defining the limits of other subclones described herein. Plasmids denoted after arrows carry deletions 5' of the indicated restriction site; plasmids denoted within parentheses carry deletions 3' of the indicated restriction site.

The predicted amino-acid sequence (Seq. No. 5) of the product of this DNA's (i.e. nucleotide 81 to 1103, or Seq. No. 4) product harpinpss according to the present invention is:

In this amino acid sequence, the amino acids that were confirmed by sequencing of the purified harpin_{PSS} are denoted in italics, the region of similarity with the *Erwinia amylovora* harpine by a single underlined (identical amino acids are in bold), and repeated amino acid sequences within harpin_{PSS} by double underlining.

The harpin_{PSS} coding sequence starts at nucleotide 81, ends at 1103, and encodes a protein of 34.7 kDA. This is smaller than the size of harpin_{PSS} estimated on SDS-PAGE gels (Figure 3), and suggests that the protein might migrate abnormally in these gels. This was

confirmed by a more accurate measurement of molecular mass using a mass spectrometer (Lasermat, Finnigan Mat), which estimated harpin_{PSS} to be 34.7 kDa and harpin_{PSS}Δ125 to be 25.1 kDa, in close agreement with the sequence predictions. Amino terminal sequencing of purified harpin_{PSS} and harpin_{PSS}Δ125 confirmed the start codon of harpin_{PSS} and revealed, as predicted by the sequence data, that harpin_{PSS}Δ125 has the N-terminal sequence of β-galactosidase, and is therefore a fusion protein.

Harpin_{PSS} has no significant sequence similarity with sequences deposited in major sequence databases accessible with the Blast search program [see J. Mol. Biol. 215:403 (1990)]; nor were motifs of known biological significance detected for harpin_{PSS} using the MOTIF program in the Genetics Computer Group Sequence Analysis Software Package [see Gene 12:387 (1984)]. However, an intriguing, albeit limited, sequence similarity was detected between harpin_{PSS} and harpin_{Ea} over a stretch of 22 amino acids. Harpin_{PSS} is rich in glycine (13.5%) and lacks cysteine and tyrosine. The amino terminal sequence of harpin_{PSS} is unlike typical sequences that would target proteins for translocation across the bacterial cytoplasmic membrane via the Sec export pathway. No obvious transmembrane, hydrophobic sequences are present in harpin_{PSS}. In fact harpin_{PSS} appears to be highly hydrophilic and is a soluble cytoplasmic protein when expressed in *E. coli*. Because the gene encoding harpin_{PSS} showed little relationship with the *hrpN* gene of *Erwinia amylovora* and encodes the apparent end product of the *P.s.syringae* 61 hrp cluster, it was designated *hrpZ*.

The carboxyl-terminal 148 amino acid portion of harpin_{PSS} was found to contain two directly repeated sequences and is sufficient for elicitor activity. The two sequences, GGGLGTP (Seq. No. 1) and QTGT (Seq. No. 2), are directly repeated in the portion of harpin_{PSS} that is carboxyl-terminal to the 22 amino acid region showing similarity to harpin_{Ea}. To assess the importance of these features of harpin_{PSS} in elicitor activity, a series of deletions were constructed in *hrpZ*. Figure 2 depicts the *hrpZ* restriction sites that were exploited in the construction of subclones and deletion derivatives and the resulting

truncated harpin_{PSS} polypeptides. Immunoblot analysis with anti-harpin_{PSS} antibodies confirmed the production of polypeptides of the predicted sizes by the various plasmids. *E. coli* DH5 α cells carrying the plasmids were sonicated in the presence of PMSF, and soluble extracts
5 were infiltrated into tobacco leaves. The differing effects of the polypeptides produced by pSYH14 demonstrated that the region of similarity with harpin_{Ea} was neither sufficient nor necessary for elicitor activity. In contrast, a typical HR was elicited within 24 hr by all polypeptides carrying both of the repeated sequences. The effects
10 of the polypeptides produced pSYH33 further suggest that both pairs of repeated sequences are essential for elicitor activity.

Southern Blot and Immunoblot analyses suggest that a *hrpZ* homolog is present and expressed in other *P. syringae* pathovars. To determine whether *hrpZ* sequences were present in other pathovars
15 of *Pseudomonas syringae*, we used the BstXI fragment that is within *hrpZ* to probe a Southern blot of EcoRI-digested genomic DNA from *Pseudomonas syringae* pv *syringae* B728a, *Pseudomonas syringae* tomato DC3000, and *Pseudomonas syringae* glycinea race 4. These three strains were chosen because they represent diverse *Pseudomonas syringae*
20 pathovars that are experimentally attractive. *Pseudomonas syringae* pv *syringae* B728a causes brown spot of bean and has become an acceptable model by plant pathologists for studying epiphytic fitness in *Pseudomonas syringae*; *Pseudomonas syringae* tomato DC3000 causes a bacterial speck of tomato and is also pathogenic on several ecotypes of
25 *Arabidopsis thaliana*; and *Pseudomonas syringae* pv *glycinea* race 4 causes bacterial blight of soybean. The latter two strains are particularly useful for studying the phenomenon of avr gene-dependent (gene-for-gene) incompatibility. As seen in Figure 5, a single band from each of these pathogens hybridized to the *hrpZ* probe, suggesting
30 that the gene is widespread in *Pseudomonas syringae*. But the intensities of the hybridization signal varied, being strongest for *Pseudomonas syringae* pv *syringae* B728a, which is the strain most closely related to *Pseudomonas syringae* pv *syringae* 61. We also

probed for the presence of *hrpZ* homolog in *X.c. glycines*, but observed no hybridization (Figure 5, lane 5).

The production of proteins that cross-react with anti-harpin_{SS} was also assayed. Cells were grown in *hrp*-derepressing minimal medium for 24 hr and sonicated directly in the culture medium. The resultant lysates were analyzed by immunoblotting an SDS-PAGE gel. As shown in Figure 6, cross-reacting bands were detected in all three strains of *Pseudomonas syringae*, but not in the nonpathogen *Pseudomonas fluorescens*.

Several higher plants, in addition to tobacco, were tested for their response to harpin_{SS}, and different plants were found to exhibit different levels of sensitivity to harpin_{SS}. These included two solanaceous plants (tomato and potato), two legumes (bean and soybean), and the model crucifer, *A. thaliana*. Harpin_{SS}Δ125 and harpin_{SS} in 5 mM phosphate buffer (pH 6.5) elicited the HR in leaves of potato (> 0.6 μM and > 2.4 μM respectively) and tomato (> 5 μM and > 20 μM, respectively) within 7 to 16 hr, depending on the elicitor concentrations used. Harpin_{SS}Δ125 also elicited the HR in leaves of soybean (>50μM) and *A. thaliana* (> 50 μM). No response was observed in leaves of bean (the host plant of *Pseudomonas syringae* pv *syringae* 61) at a concentration of 60 μM with either harpin_{SS}Δ125 or harpin_{SS}. Under the current assay conditions (without protease inhibitors) the HR in soybean and *A. thaliana* leaves were not observed consistently in response to harpin_{SS} and it varied from leaf to leaf. The different responses of different plants to harpin_{SS} may indicate that some plants such as soybean, *A. thaliana*, and bean have lower sensitivity to harpin_{SS} or degrade harpin_{SS} more rapidly, or both. It is important to note here that the response of these plant species to purified harpin_{SS} are correlated with their responses to harpin_{SS} producing bacteria, but that harpin_{SS} delivered by living bacteria appears to be more effective. For example, *Pseudomonas fluorescens* 55(pHlr11) elicited a visible HR in tobacco leaves at a lower cell density 1×10^7 cells/ml than it did in *A. thaliana* leaves (> 1×10^8 cells/ml). At > 5×10^8

cells/ml, *Pseudomonas fluorescens* 55(pHIR11) weakly induced tissue necrosis in bean leaves.

The HR elicited by harpin_{PS} in tobacco was also found to be an active response of the plant. To see whether the HR induced by harpin_{PS} results from a directly toxic effect or from elicitation of an active response leading to necrosis, various inhibitors of plant metabolism were examined to determine if they could prevent the HR. Furthermore, the availability of purified harpin_{PS} enables inhibitors of plant metabolism to be used in the absence of possible interference with bacterial metabolism or hrp gene expression. The four inhibitors employed were α -amanitin (a specific inhibitor of eukaryotic RNA polymerase II), cycloheximide (a specific inhibitor of 80S ribosomes), vanadate (an inhibitor of ATPase and phosphatase), and lanthanum (a calcium channel blocker). All four inhibitors were found to effectively prevent the HR elicited harpin_{PS} in tobacco leaves when they were co-infiltrated with the purified protein at the concentrations of 2.2×10^{-4} M for α -amanitin, 7.1×10^{-5} M for cycloheximide, 5×10^{-5} M for vanadate, and 1×10^{-3} M for lanthanum. It is not known what concentrations of the inhibitors were inside plant cells during the experiment period (16-24 hr), nevertheless, the experiment clearly showed the harpin_{PS} elicited HR is an active process and may require the following important metabolic processes: *de novo* gene expression and protein synthesis, calcium flux across membranes, and ATPase activity. Thus harpin_{PS} acts as an elicitor of hypersensitivity, rather than as a directly toxic agent.

It has also been determined by the present invention that strong evidence exists indicating that Harpin_{PS} is the *Pseudomonas syringae* pv *syringae* 61 HR Elicitor.

We had previously observed that Tn_{phoA} insertions in all of the *hrp* complementation groups in the *Pseudomonas syringae* pv *syringae* 61 *hrp* cluster produce the null phenotype of a nonpathogenic bacterium [see Mol. Plant-Microbe Interact. 4:469 (1991)]. That is, the mutants fail to cause the HR in nonhost tobacco leaves to multiply or produce watersoaked, necrotic lesions in host bean leaves. On this basis, we

postulated that the *hrp* genes are involved in the production of a single factor that is essential for *Pseudomonas syringae* pv *syringae* 61 to interact with plants. Several lines of evidence now indicate that harpin_{PS} is the active factor. First, harpin_{PS} is sufficient to elicit
5 the HR in tobacco (the only phenotypic attribute that can be assayed in the absence of the bacterium); second, no other *hrp* genes in the expression library of pHIRII subclones possessed HR elicitor activity; third, harpin_{PS} is apparently essential for *Pseudomonas syringae* pv *syringae* 61 to elicit the HR in tobacco because mutations in
10 complementation group XII (*hrpZ*) produce the typical null phenotype, whereas a residual effect on the plant would be expected if another elicitor were produced by the *hrp* cluster; fourth, an extracellular location for harpin_{PS} is consistent with its function as an elicitor and argues against an alternative role in the regulation or secretion of
15 some other *hrp* product; and finally, harpin_{PS} is tightly regulated. This is consistent with the observation [see Science 245:1374 (1989)] that *Pseudomonas syringae* pv *glycinea* cells grown in minimal medium and treated with rifampicin upon inoculation can still elicit the HR, whereas cells grown in rich medium cannot do this. Additional
20 characteristics predicted for the harpin are discussed below.

The finding that unrelated proteins of *Erwinia amylovora* and *Pseudomonas syringae* pv *syringae* elicit the HR suggests a working definition based on their common properties. Thus, harpins are *hrp*-
25 encoded proteins that are hydrophilic, lack amino-terminal signal peptides, are heat stable, and elicit hypersensitive necrosis in many plants. Furthermore, we have shown here that harpin_{PS} is secreted into the bacterial medium via the Hrp secretory pathway, that the carboxyl-terminal 43% of the protein is sufficient for elicitor activity, and that the hypersensitivity of tobacco to harpin_{PS} is an active
30 response of the plant.

Additional structural features of harpin_{PS} are noteworthy. First, the amino-acid composition of harpin_{PS} is generally similar to that of harpin_{Ea}. For example, both proteins are rich in glycine and lack cysteine. This suggests that the proteins have an open structure and is

consistent with their resistance to denaturation by heat and their solubility in trichloroacetic acid. Interestingly, the 148 amino acid product of pSYH14, which is the smallest polypeptide we constructed with elicitor activity, is particularly high in glycine (20%); second, the two harpins lack any stretches of hydrophobic amino acids that would serve as an inner membrane anchor; third, the two harpins carry an internal sequence in which 11 of 22 amino acids are identical (although this level of similarity does not reliably predict structural homology [see Genetics 9:56 (1991)], this region would be a candidate targeting signal for *hrp*-dependent translocation to the bacterial surface); fourth, two sequences, GGGLGTP and QTGT, are directly repeated in a carboxyl-terminal region of harpinP_{SS} (although such repeated sequences are lacking harpinE_a they apparently are required for the elicitor activity of harpinP_{SS}; deletions affecting one member of either pair abolished elicitor activity (Figure 2)); fifth, harpinP_{SS} lacks tyrosine, and while it is tempting to speculate that this facilitates passage of the protein through the plant cell wall when H₂O₂-mediated cross-linking of tyrosine residue in cell wall proteins (a potential defense response) occurs, the lack of tyrosine residues is apparently not a universal characteristic of harpins, as harpinE_a has four [see Science 257:85 (1992)].

A fundamental question concerning the relationship between harpinP_{SS} structure and function is whether the protein is an enzyme (with a substrate in the plant cell wall, for example) whose product is the actual elicitor, or whether the plant responds to information residing in the harpin structure itself; our hypothesis is that the latter is correct. For example, harpinP_{SS} shows no pectolytic activity (pectic enzymes also can kill plant cells, but reports suggesting a role in elicitation of the HR have not been supported by subsequent genetic analysis), nor has any elicitor activity been found in protease-treated apoplastic fluids that have been recovered by centrifugation [see Physiol. Plant Pathol. 21:1 (1982)] from harpinP_{SS}-treated tobacco leaves. Furthermore, the heat stability of harpinP_{SS} and the retention

of activity in a truncated derivative lacking more than half of the native protein are properties that are uncharacteristic of enzymes.

The *hrp* clusters of *Pseudomonas syringae*, *Pseudomonas solanacearum*, *X. campestris* and *Erwinia amylovora* contain putative
5 open reading frames for proteins similar to components of a secretion pathway in *Yersinia spp.* and other human pathogens [see Mol. Plant-Microbe Interact. 5:390 (1992); and Mol. Plant-Microbe Interact. 5:384 (1992)]. The pathway is used by several extracellular, virulence ("Yop") proteins, all of which lack amino-terminal signal peptides and any
10 other consensus targeting sequences [J. Bacteriol. 173:1677 (1991)]. The secretion of the Yop proteins to the medium and the virulence of *Yersinia spp.* are dependent on this pathway, which is encoded, at least in part, by a *ysc* (Yop secretion) operon. The similarities between the secretion pathway (components of these animal and plant pathogens has
15 suggested that some of the *hrp* genes control the secretion of Yop-like proteins. Our finding that the *Pseudomonas syringae pv syringae* 61 HrpH protein (a YscC homolog) is required for harpin_{PS} secretion, provides direct experimental evidence for this hypothesis. The presence of YscC homologs in *Pseudomonas solanacearum* and *X.*
20 *campestris* suggests that these bacteria also produce harpins. The likely universality of harpins among plant pathogenic bacteria that elicit the HR in nonhosts finds further experimental support in that *Pseudomonas solanacearum* produces one or more heat-stable, protease-sensitive factors that are secreted by Hrp⁺ cells and elicit
25 HR-like necrosis in tobacco.

Despite the conservation of the *hrp* secretion genes, the genes encoding the harpins do not appear to be conserved among different genera of plant pathogenic bacteria. The lack of conservation is indicated by the dissimilarity of the *Erwinia amylovora hrpN* and
30 *Pseudomonas syringae pv syringae hrpZ* genes and the failure of *hrpZ* to hybridize with the genomic DNA of *X. campestris*, a species whose diverse interactions with plants parallel those of *Pseudomonas syringae*.

Plant hypersensitivity to bacterial pathogens is generally considered to be an active response of the plant. Hypersensitive necrosis occurs many hours after inoculation, it does not require living bacteria once a relatively brief induction period has passed, and can be inhibited by darkness, high temperatures, protein synthesis inhibitors such as blasticidin S, and calcium channel blockers such as cobalt and lanthanum. Although these treatments may have potentially confounding effects on bacterial metabolism and/or *hrp* gene expression, *in toto*, they strongly indicate that the *Pseudomonas syringae* HR elicitor acts in a nonhost as a signal that triggers a plant defense response pathway, rather than a toxic agent that directly kills plant cells. As described above, the necrosis elicited in tobacco leaves by harpin_{SS} does indeed require *de novo* transcription, translation, calcium influx, and ATPase activity. The similar effect on plants of living *Pseudomonas syringae* cells and isolated harpin_{SS} provides further evidence that *Pseudomonas syringae* elicits the HR solely through its production of extracellular harpin_{SS}. An important implication of these findings is that gene expression events, specific transcripts, and mutants blocked in the plant signal transduction pathway controlling hypersensitivity can now be pursued in the absence of bacteria.

The uses to which the various aspects and portions of the present invention may be put to are many and varied. For example, *hrpZ* mutants may be used to identify, by complementation, genes from other plant pathogenic organisms (e.g., bacteria, fungi, nematodes) that encode proteins that function similarly to harpin. Although such proteins may have substantially different primary structures (and therefore would be difficult to detect by DNA hybridization techniques), these proteins should restore the ability to elicit the HR to either *Pseudomonas syringae* or *E. coli* cells carrying a *hrp* cluster that was functional, except for the *hrpZ* gene.

Another use within the scope of the present invention is to use harpin and/or harpin-producing strains to identify in plants harpin receptors and/or their interactants in signal transduction pathways and

clone their encoding genes. Thus, this would allow one to exploit the potential of harpin to function (depending upon the plant) as a pathogenicity factor or as an elicitor of defense reactions to manipulate the structure or expression of plant genes (s) encoding harpin receptor(s) for the purpose of producing genetically engineered plants with improved resistance to plant pathogens.

Still another use of harpin within the scope of the present invention would be as a potentiator of secondary metabolite production in plants grown either naturally or in tissue culture.

Still another use would be the fusion of the gene encoding harpin to specific promoters of plant genes to develop specific transgenic plants. When the plant gene is "turned on", harpin would be expressed and the plant cell killed. Some appropriate plant gene promoters and their projected uses include genes involved in pollen development (resulting in the development of male sterile plants); genes that are expressed in response to infection by fungi, e.g. genes encoding phenylalanine ammonia lyase and chalcone synthase (the plant cell would be killed thereby limiting the progress of the fungus and making the plant resistant to fungal diseases); and genes involved in the development of senescence (to facilitate harvest, expression of *hrp* genes would result in defoliation).

Still another use of harpin within the scope of the present invention would be the use of harpin as a "target molecule" with which chemical compounds would be designed to react and thereby inactivate the bacterial harpin, which, because it is essential for disease, would provide a specific bacteriacide target.

A listing of the nucleotide and amino acids described in the present application are as follows:

Thus while we have illustrated and described the preferred embodiment of our invention, it is to be understood that this invention is capable of variation and modification, and we therefore do not wish
 35 to be limited to the precise terms set forth, but desire to avail

ourselves of such changes and alterations which may be made for adapting the invention to various usages and conditions. Such variations and modifications, for example, would include the substitution of structurally similar sequences, for both the elicitor and
5 hrpZ genes provided herein (whether derived from natural sources or synthetically manufactured), which function to yield substantially similar activities to those specifically described above. Thus, changes in sequence by the substitution, deletion, insertion or addition of nucleic acids (in the DNA sequences) or amino acids (in the peptide
10 sequences) which do not substantially alter the function of those sequences specifically described above are deemed to be within the scope of the present invention. In addition, those fragments of the oligonucleotide sequence designated sequence No. 3 in the above sequence listing, i.e. the sequences shown as pSYH10, pSYH4, pSYH5, pSYH12, pSYH32, pSYH8, pSYH9, pSYH14, pSYH33, pSYH12, pSYH26,
15 pSYH32 and pSYH33 are deemed to be within the scope of the present invention. Accordingly, such changes and alterations are properly intended to be within the full range of equivalents, and therefore within the purview of the following claims.

20 Having thus described our invention and the manner and a process of making and using it in such full, clear, concise and exact terms so as to enable any person skilled in the art to which it pertains, or with which it is most nearly connected, to make and use the same;

We claim:

25

CLAIMS:

1. An isolated protein, corresponding to a protein expressed by *hrp* genes, that is hydrophilic, lacks amino-terminal signal peptides, is heat stable, elicits hypersensitive necrosis in plants, and comprises the amino acid sequence Gly Gly Gly Leu Gly Thr Pro and the amino acid sequence Gln Thr Gly Thr within the protein.

2. A nucleic acid sequence being a fragment selected from the whole or a fragment of the sequence

INTERNATIONAL SEARCH REPORT

 International application No.
PCT/US94/05014

A. CLASSIFICATION OF SUBJECT MATTER

IPC(S) : C07K 13/00, 15/04; C12N 1/21, 15/11, 15/31

US CL : Please See Extra Sheet.

According to International Patent Classification (IPC) or to both national classification and IPC

B. FIELDS SEARCHED

Minimum documentation searched (classification system followed by classification symbols)

U.S. : 530/350; 536/23.1, 23.7; 435/252.3, 252.33, 320.2, 69.1, 172.3, 874

Documentation searched other than minimum documentation to the extent that such documents are included in the fields searched

Electronic data base consulted during the international search (name of data base and, where practicable, search terms used)

APS, MEDLINE, BIOSIS, EMBASE, LIFESCI, WPIDS, BIOTECHDS, CA

search terms: hypersensitive response, pseudomonas syringae, harpin, necrosis

C. DOCUMENTS CONSIDERED TO BE RELEVANT

Category*	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
P, X	Cell, Volume 73, issued 02 July 1993, S.Y. He et al., "Pseudomonas syringae pv. syringae Harpin _{Pss} : A Protein That is Secreted Via the Hrp Pathway and Elicits the Hypersensitive Response in Plants", pages 1255-1266, see entire document.	1-6
P, X	Trends in Microbiology, Volume 2, No. 1, issued January 1994, U. Bonas, "Bacterial Home Goal by Harpins", pages 1-2, see entire document.	1-6
Y	Science, Volume 257, issued 03 July 1992, Z. Wei et al., "Harpin, Elicitor of the Hypersensitive Response Produced by the Plant Pathogen <i>Erwinia amylovora</i> ", pages 85-88, see entire document.	1-3, 6

☒ Further documents are listed in the continuation of Box C.
 ☐ See patent family annex.

* Special categories of cited documents:	*T	later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention
A document defining the general state of the art which is not considered to be of particular relevance	*X*	document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
E earlier document published on or after the international filing date	*Y*	document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art
L document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)	*Z*	document member of the same patent family
O document referring to an oral disclosure, use, exhibition or other means		
P document published prior to the international filing date but later than the priority date claimed		

Date of the actual completion of the international search	Date of mailing of the international search report
05 AUGUST 1994	16 AUG 1994
Name and mailing address of the ISA/US Commissioner of Patents and Trademarks Box PCT Washington, D.C. 20231	Authorized officer REBECCA PROUTY <i>Jill Warden for</i>
